

# Chapter 1

## Isoperimetric inequality

For any plane figure  $F$  with perimeter  $\ell$ , its area  $a$  satisfies the following inequality:

$$\textcircled{1} \qquad 4\pi \cdot a \leq \ell^2.$$

Moreover the equality holds iff  $F$  is congruent to a round disk.

This is the so-called *isoperimetric inequality* on the plane. Let us restate it without formulas, using the comparison language.

**1.1. Isoperimetric inequality.** *The area of a plane figure bounded by a closed curve of length  $\ell$  can not exceed the area of a round disk with the same circumference  $\ell$ . Moreover the equality holds only if the figure is congruent to the disk.*

The comparison reformulation has some advantages — it is more intuitive and it is also easier to generalize.

**1.2. Exercise.** *Come up with a formulation of the isoperimetric inequality on the unit sphere. Try to reformulate it as an algebraic inequality similar to  $\textcircled{1}$ .*

Recall that a plane figure  $F$  is called *convex* if for every pair of points  $x, y \in F$ , the line segment  $[x, y]$  that joins the pair of points lies also in  $F$ .

The following exercise reduces the isoperimetric inequality to the case of convex figures:

**1.3. Exercise.** Assume  $F$  is a plane figure bounded by a closed curve of length  $\ell$ . Show that there is a convex figure  $F' \supset F$  bounded by a closed curve of length at most  $\ell$ .

The following problem is named after Dido, the legendary founder and first queen of Carthage.

**1.4. Dido's problem.** The figure of maximal area bounded by a straight line and a curve of given length with endpoints on that line is a half-disk.

**1.5. Exercise.** Show that Dido's problem follows from the isoperimetric inequality and the other way around.

**1.6. Exercise.** Use the isoperimetric inequality in the plane to show that among all the polygons with given sides, the convex polygons inscribed in a circle have maximal area.

**1.7. Exercise.** Find the minimal length of a curve that divides the unit square in a given ratio  $\alpha$ .

## 1.1 Lawlor's proof

Here we present a sketch of the proof of Dido's problem based on the idea of Gary Lawlor in [1]. Before getting into the proof, try to solve the following exercise.

**1.8. Exercise.** An old man walks along a trail around a convex meadows and pulls a brick tied to a rope of unit length (the rope is always strained). After walking around he noticed that the brick is at the same position as at the beginning. Show that the area between the trail and the path of the brick equals the area of the unit disk.

*Sketch of the proof.* Let  $F$  be a convex figure bounded by a line and a curve  $\gamma(t)$  of length  $\ell$ ; we can assume that  $\gamma$  is a unit speed curve so the set of parameters is  $[0, \ell]$ .

Imagine that we are walking along the curve with a stick of length  $r$  so that the other end of the stick drags as we walk. Assume that initially at  $t = 0$  the stick points in the direction of  $\gamma(\ell)$  — the other end of  $\gamma$ .

Note that if  $r$  is small then most of the time we drag the stick behind. Therefore at the end of the walk the stick will have made more than half turn and will point to the same side of the figure.

Let  $R$  be the radius of the half-circle  $\tilde{\gamma}(t)$  of length  $\ell$ . Assume we walk along  $\tilde{\gamma}$  with a stick of length  $R$  the same way as described above. Note that the other end does not move (it always lies in the center) and the direction of the stick changes with rate  $\frac{1}{R}$ . Note further that for  $\gamma$  this rate is at most  $\frac{1}{R}$ . Therefore after walking along  $\gamma$ , the stick of length  $R$  will rotate at most as much as if we walk along  $\tilde{\gamma}$ .

It follows that there is a positive value  $r \leq R$  such that after walking along  $\gamma$  with a stick of length  $r$ , it will rotate exactly half turn, so at the end it will point towards  $\gamma(0)$ .

Imagine that the stick of length  $r$  is covered with red paint and it paints the area below it. If we move with velocity  $v$  then the angular velocity (radians per second) of the stick is at most  $\frac{v}{r}$  and the equality holds if we move perpendicularly to the stick. Therefore we paint at a rate of at most  $\frac{1}{2}v \cdot r$ .

If we do the same for the half-disk of radius  $R$  and a stick of length  $R$  with blue paint, then we paint the area of the disk without overlap with the rate  $\frac{1}{2}v \cdot R$ . Since  $r \leq R$ , the total red-painted area can not exceed the blue-painted area, that is,  $D$ .

It remains to show that all  $F$  is red-painted. Fix a point  $p \in F$ . Notice that at the beginning the point  $p$  lies on the left from the stick and at the end it lies on the right from it. Therefore there will be a moment  $t_0$  when the side changes from left to right. At this time the point must be on the line containing the stick. Moreover, if it lies on the extension then the side changes from right to left. Therefore  $p$  has to lie under the stick; that is,  $p$  is painted. □

**1.9. Exercise.** Find the steps with cheating in the above proof and try to fix them.

**1.10. Exercise.** Read and understand the original proof of Gary Lawlor in [1].

# Chapter 2

## Length

The material of this and the following chapters overlaps largely with [2, Chapter 5].

### 2.1 Length of curve

**2.1. Definition.** Consider a plane curve  $\alpha: [a, b] \rightarrow \mathbb{R}^2$ ; a continuous mapping from the real interval  $[a, b]$  to the Euclidean plane  $\mathbb{R}^2$ .

If  $\alpha(a) = p$  and  $\alpha(b) = q$ , we say that  $\alpha$  is a curve from  $p$  to  $q$ .

A curve  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  is called closed if  $\alpha(a) = \alpha(b)$ .

A curve  $\alpha$  is called simple if it is described by an injective map; that is  $\alpha(t) = \alpha(t')$  if and only if  $t = t'$ . However, a closed curve  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  is called simple if it is injective everywhere except at the ends; that is, if  $\alpha(t) = \alpha(t')$  for  $t < t'$  then  $t = a$  and  $t' = b$ .

**2.2. Exercise.** Let  $\alpha: [0, 1] \rightarrow \mathbb{R}^2$  from  $p$  to  $q$ . Assume  $p \neq q$ . Show that there is a simple curve  $\beta: [0, 1] \rightarrow \mathbb{R}^2$  from  $p$  to  $q$  that runs in the image of  $\alpha$ ; that is for any  $t \in [0, 1]$  there is  $t' \in [0, 1]$  such that  $\beta(t) = \alpha(t')$ .

Recall that a sequence

$$a = t_0 < t_1 < \cdots < t_k = b.$$

is called a *partition* of the interval  $[a, b]$ .

**2.3. Definition.** Let  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  be a curve. The length of  $\alpha$  is defined as

$$\text{length } \alpha = \sup\{|\alpha(t_0) - \alpha(t_1)| + |\alpha(t_1) - \alpha(t_2)| + \dots \\ \dots + |\alpha(t_{k-1}) - \alpha(t_k)|\}.$$

where the exact upper bound is taken over all partitions

$$a = t_0 < t_1 < \dots < t_k = b.$$

Note that  $\text{length } \alpha \in [0, \infty]$ ; the curve  $\alpha$  is called *rectifiable* if its length is finite.

Informally, one could say that the length of a curve is the exact upper bound of the lengths of polygonal lines *inscribed* in the curve.

**2.4. Exercise.** Assume  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  is a smooth curve, in particular the velocity vector  $\alpha'(t)$  is defined and depends continuously on  $t$ . Show that

$$\text{length } \alpha = \int_a^b |\alpha'(t)| \cdot dt.$$

**2.5. Exercise.** Construct a nonrectifiable curve  $\alpha: [0, 1] \rightarrow \mathbb{R}^2$ .

A closed simple plane curve is called *convex* if it bounds a convex figure.

**2.6. Proposition.** Assume a convex figure  $A$  bounded by a curve  $\alpha$  lies inside a figure  $B$  bounded by a curve  $\beta$ . Then

$$\text{length } \alpha \leq \text{length } \beta.$$

Note that it is sufficient to show that for any polygon  $P$  inscribed in  $\alpha$  there is a polygon  $Q$  inscribed in  $\beta$  with  $\text{perim } P \leq \text{perim } Q$ , where  $\text{perim } P$  denotes the perimeter of  $P$ .

Therefore it is sufficient to prove the following lemma.

**2.7. Lemma.** Let  $P$  and  $Q$  be polygons. Assume  $P$  is convex and  $Q \supset P$ . Then  $\text{perim } P \leq \text{perim } Q$ .

*Proof.* Note that by the triangle inequality, the inequality

$$\text{perim } P \leq \text{perim } Q$$

holds if  $P$  can be obtained from  $Q$  by cutting it along a chord; that is, a line segment with ends on the boundary of  $Q$  that lies in  $Q$ .

Note that there is an increasing sequence of polygons

$$P = P_0 \subset P_1 \subset \cdots \subset P_n = Q$$

such that  $P_{i-1}$  obtained from  $P_i$  by cutting along a chord. Therefore

$$\begin{aligned} \text{perim } P &= \text{perim } P_0 \leq \text{perim } P_1 \leq \cdots \\ &\cdots \leq \text{perim } P_n = \text{perim } Q \end{aligned}$$

and the lemma follows.  $\square$

**2.8. Corollary.** *Any convex closed curve is rectifiable.*

*Proof.* Fix a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^2$ . Note that  $\alpha$  is bounded; indeed

Any closed curve is bounded; that is, it lies in a sufficiently large square.

By Proposition 2.6, the length of the curve can not exceed the perimeter of the square, hence the result.  $\square$

## 2.2 Semicontinuity of length

Recall that the lower limit of a sequence of real numbers  $(x_n)$  is denoted by

$$\liminf_{n \rightarrow \infty} x_n.$$

It is defined as the lowest partial limit; that is, the lowest possible limit of a subsequence of  $(x_n)$ . The lower limit is defined for any sequence of real numbers and it lies in the extended real line  $[-\infty, \infty]$

**2.9. Theorem.** *Length is a lower semi-continuous with respect to pointwise convergence of curves.*

*More precisely, assume that a sequence of curves  $\alpha_n: [a, b] \rightarrow \mathbb{R}^2$  converges pointwise to a curve  $\alpha_\infty: [a, b] \rightarrow \mathbb{R}^2$ ; that is,  $\alpha_n(t) \rightarrow \alpha_\infty(t)$  for any fixed  $t \in [a, b]$  as  $n \rightarrow \infty$ . Then*

$$\textcircled{1} \quad \liminf_{n \rightarrow \infty} \text{length } \alpha_n \geq \text{length } \alpha_\infty.$$

Note that the inequality  $\textcircled{1}$  might be strict. For example the diagonal  $\alpha_\infty$  of the unit square

can be approximated by a sequence of stairs-like polygonal curves  $\alpha_n$  with sides parallel to the sides of the square ( $\alpha_6$  is on the picture). In this case

$$\text{length } \alpha_\infty = \sqrt{2} \quad \text{and} \quad \text{length } \alpha_n = 2$$

for any  $n$ .

*Proof.* Fix  $\varepsilon > 0$  and choose a partition  $a = t_0 < t_1 < \cdots < t_k = b$  such that

$$\text{length } \alpha_\infty < |\alpha_\infty(t_0) - \alpha_\infty(t_1)| + \cdots + |\alpha_\infty(t_{k-1}) - \alpha_\infty(t_k)| + \varepsilon.$$

Set

$$\begin{aligned}\Sigma_n &:= |\alpha_n(t_0) - \alpha_n(t_1)| + \cdots + |\alpha_n(t_{k-1}) - \alpha_n(t_k)|. \\ \Sigma_\infty &:= |\alpha_\infty(t_0) - \alpha_\infty(t_1)| + \cdots + |\alpha_\infty(t_{k-1}) - \alpha_\infty(t_k)|.\end{aligned}$$

Note that  $\Sigma_n \rightarrow \Sigma_\infty$  as  $n \rightarrow \infty$  and  $\Sigma_n \leq \text{length } \alpha_n$  for each  $n$ . Hence

$$\lim_{n \rightarrow \infty} \text{length } \alpha_n \geq \text{length } \alpha_\infty - \varepsilon.$$

Since  $\varepsilon > 0$  is arbitrary, we get **1**. □

## 2.3 Axioms of length

**Concatenation.** Assume  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  and  $\beta: [b, c] \rightarrow \mathbb{R}^2$  are two curves such that  $\alpha(b) = \beta(b)$ . Then one can combine these two curves into one  $\gamma: [a, c] \rightarrow \mathbb{R}^2$  by the rule  $\gamma(t) = \alpha(t)$  for  $t \leq b$  and  $\gamma(t) = \beta(t)$  for  $t \geq b$ . The obtained curve  $\gamma$  is called the *concatenation* of  $\alpha$  and  $\beta$  and is denoted as  $\gamma = \alpha * \beta$ .

Note that

$$\text{length}(\alpha * \beta) = \text{length } \alpha + \text{length } \beta$$

for any two curves  $\alpha$  and  $\beta$  such that the concatenation  $\alpha * \beta$  is defined.

**Reparametrization.** Assume  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  is a curve and  $\tau: [c, d] \rightarrow [a, b]$  is a continuous strictly monotonic onto map. Consider the curve  $\alpha': [c, d] \rightarrow \mathbb{R}^2$  defined by  $\alpha' = \alpha \circ \tau$ . The curve  $\alpha'$  is called a *reparametrization* of  $\alpha$ .

Note that

$$\text{length } \alpha' = \text{length } \alpha$$

whenever  $\alpha'$  is a reparametrization of  $\alpha$ .

**2.10. Proposition.** Let  $\ell$  be a functional that returns a value in  $[0, \infty]$  for any curve  $\alpha: [a, b] \rightarrow \mathbb{R}$ .

Assume it satisfies the following properties:

(i) (Normalization) If  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  is a linear curve,<sup>1</sup> then

$$\ell(\alpha) = |\alpha(a) - \alpha(b)|.$$

(ii) (Additivity) If the concatenation  $\alpha * \beta$  is defined, then

$$\ell(\alpha * \beta) = \ell(\alpha) + \ell(\beta).$$

(iii) (Motion invariance) The functional  $\ell$  is invariant with respect to the motions of the plane; that is, if  $m$  is an isometry of the plane, then

$$\ell(m \circ \alpha) = \ell(\alpha)$$

for any curve  $\alpha$ .

(iv) (Reparametrization invariance) If  $\alpha'$  is a reparametrization of a curve  $\alpha$  then

$$\ell(\alpha') = \ell(\alpha).$$

(In fact linear reparametrizations will be sufficient.)

(v) (Semi-continuity) If a sequence of curves  $\alpha_n: [a, b] \rightarrow \mathbb{R}^2$  converges pointwise to a curve  $\alpha_\infty: [a, b] \rightarrow \mathbb{R}^2$ , then

$$\liminf_{n \rightarrow \infty} \ell(\alpha_n) \geq \ell(\alpha_\infty).$$

Then

$$\textcircled{2} \quad \ell(\alpha) = \text{length } \alpha$$

for any plane curve  $\alpha$ .

*Proof.* Note that from normalization and additivity, the identity

$$\textcircled{3} \quad \ell(\beta) = \text{length } \beta$$

holds for any polygonal line  $\beta$  that is linear on each edge.

Note that the following two inequalities

$$\textcircled{4} \quad \ell(\alpha) \leq \text{length } \alpha$$

$$\textcircled{5} \quad \ell(\alpha) \geq \text{length } \alpha$$

imply  $\textcircled{2}$ ; we will prove them separately.

Fix a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  and a partition  $a = t_0 < t_1 < \dots < t_k = b$ . Consider the curve  $\beta: [a, b] \rightarrow \mathbb{R}^2$  defined as the linear

---

<sup>1</sup>That is  $\alpha = w + v \cdot t$  for some vectors  $w$  and  $v$ .

segment from  $\alpha(t_i)$  to  $\alpha(t_{i+1})$  on each interval  $t \in [t_i, t_j]$ . By the definition of length,

$$\text{length } \beta \leq \text{length } \alpha.$$

Since the map  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  is continuous, one can find a sequence of partitions of  $[a, b]$  such that the corresponding curves  $\beta_n$  converge to  $\alpha$  pointwise. Applying the semi-continuity of  $\ell$ , ❸ and the definition of length, we get that

$$\begin{aligned} \ell(\alpha) &\leq \varliminf_{n \rightarrow \infty} \ell(\beta_n) = \\ &= \varliminf_{n \rightarrow \infty} \text{length } \beta_n \leq \\ &\leq \text{length } \alpha. \end{aligned}$$

Hence ❹ follows.

Note that a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  with a partition  $a = t_0 < t_1 < \dots < t_k = b$  can be considered as a concatenation

$$\alpha = \alpha_1 * \alpha_2 * \dots * \alpha_k$$

where  $\alpha_i$  is the restriction of  $\alpha$  to  $[t_{i-1}, t_i]$ .

Observe that there is a sequence of motions  $m_i$  of the plane so that

$$m_i \circ \alpha(t_i) = m_{i+1} \circ \alpha(t_i)$$

for any  $i$  and the points

$$m_1 \circ \alpha(t_0), m_1 \circ \alpha(t_1), \dots, m_k \circ \alpha(t_k)$$

lie in that order on a single line. For the concatenation

$$\gamma = (m_1 \circ \alpha_1) * (m_2 \circ \alpha_2) * \dots * (m_k \circ \alpha_k)$$

we have

$$\ell(\gamma) = \ell(\alpha).$$

Note that one can find a sequence of partitions of  $[a, b]$  such that reparametrizations of  $\gamma_n$  converge to a linear segment  $\gamma'_\infty$ ; denote these reparametrizations by  $\gamma'_n$ . Also,  $\text{length } \gamma'_\infty = \text{length } \alpha$ ; indeed, since  $\gamma'_\infty$  is linear,

$$\begin{aligned} \text{length } \gamma'_\infty &= |\gamma'_\infty(a) - \gamma'_\infty(b)| = \\ &= \lim_{n \rightarrow \infty} \Sigma_n = \\ &= \text{length } \alpha. \end{aligned}$$

where  $\Sigma_n$  is the sum in the definition of length for the  $n$ -th partition. Hence it is sufficient to choose a sequence of partitions such that  $\Sigma_n \rightarrow \text{length } \alpha$ .

Applying additivity, invariance of  $\ell$  with respect to motions and reparametrizations, we get that

$$\begin{aligned}\ell(\alpha) &= \lim_{n \rightarrow \infty} \ell(\gamma_n) = \\ &= \lim_{n \rightarrow \infty} \ell(\gamma'_n) \geq \\ &\geq \ell(\gamma'_\infty) = \\ &= \text{length } \alpha.\end{aligned}$$

Hence ⑤ follows. □

**2.11. Exercise.** *Construct a functional  $\ell$  that satisfies all the conditions in Proposition 2.10 except the semi-continuity.*

## 2.4 Crofton formula

Let  $\alpha$  be a plane curve and  $u$  a unit vector. Denote by  $\alpha_u$  the orthogonal projection of  $\alpha$  to a line  $\ell$  in the direction of  $u$ ; that is,  $\alpha_u(t) \in \ell$  and  $\alpha(t) - \alpha_u(t) \perp \ell$  for any  $t$ .

**2.12. Crofton formula.** *The length of any plane curve  $\alpha$  is proportional to the average of the lengths of its projections  $\alpha_u$  for all unit vectors  $u$ . Moreover for any plane curve  $\alpha$  we have*

$$\text{length } \alpha = \frac{\pi}{2} \cdot \overline{\text{length } \alpha_u},$$

where  $\overline{\text{length } \alpha_u}$  denotes the average value of  $\text{length } \alpha_u$ .

*Proof.* First let us show that the formula

$$\text{⑥} \quad \text{length } \alpha = k \cdot \overline{\text{length } \alpha_u},$$

holds for some fixed coefficient  $k$ . It will follow once we show that both sides of formula satisfy the length axioms in 2.10.

The normalization can be achieved by adjusting  $k$ .

The semi-continuity of the right hand side follows since  $\text{length } \alpha_u$  is semi-continuous and therefore the average has to be semi-continuous.

It is straightforward to check the remaining properties.

It remains to find  $k$ . Let us apply the formula ⑥ to the unit circle. The circle has length  $2 \cdot \pi$  and its projection to any line has length 4

— it is a segment of length 2 traveled back and forth. Evidently the average value is also 4, so

$$2 \cdot \pi = k \cdot 4,$$

hence  $k = \frac{\pi}{2}$ . □

**Reformulation via number of intersections.** Given a unit vector  $u$  and a real number  $\rho$ , consider the line of vectors  $w$  on the plane satisfying the equation

$$\langle u, w \rangle = \rho,$$

where  $\langle u, w \rangle$  denotes the scalar product. Any line on the plane admits exactly two such presentations with pairs  $(u, \rho)$  and  $(-u, -\rho)$ . A pair  $(u, \rho)$  describes uniquely an *oriented* lines — that is a line with a chosen unit normal vector.

Fix a unit vector  $u_0$  and denote by  $u(\varphi)$  the result of rotating  $u_0$  counterclockwise by the angle  $\varphi$ . Denote by  $\ell(\varphi, \rho)$  the oriented line associated to the pair  $(u(\varphi), \rho)$ . To describe any line, we need a pair  $(\varphi, \rho) \in (-\pi, \pi] \times \mathbb{R}$ .

For a curve  $\alpha$ , set  $n_\alpha(\varphi, \rho)$  to be the number of parameter values  $t$  such that  $\alpha(t)$  lies on the line  $\ell(\varphi, \rho)$ . The value  $n_\alpha(\varphi, \rho)$  is a non-negative integer or  $\infty$ . Note that if  $\alpha$  is a simple curve, then  $n_\alpha(\ell)$  is the number of intersections of  $\alpha$  with  $\ell$ .

**2.13. An other Crofton formula.** *For any curve  $\alpha$ ,*

$$\text{length } \alpha = \frac{1}{4} \cdot \iint_{(-\pi, \pi] \times \mathbb{R}} n_\alpha(\rho, \varphi) \cdot d\rho \cdot d\varphi.$$

*the integral is to be understood in the sense of Lebesgue.*

By definition of average value,

$$\overline{\text{length } \alpha_u} = \frac{1}{2 \cdot \pi} \cdot \int_{-\pi}^{\pi} \text{length } \alpha_{u(\varphi)} \cdot d\varphi.$$

Therefore the proof of this reformulation of the Crofton follows from the following observation.

**2.14. Observation.** *If  $u = u(\varphi)$ , then*

$$\text{length } \alpha_u = \int_{\mathbb{R}} n_\alpha(\rho, \varphi) \cdot d\rho;$$

The proof is straightforward for those who understand Lebesgue integral.

**Variations.** The same argument can be used to derive other formulas of the same type. For example.

Recall that a big circle in a sphere is the intersection of the sphere with a plane passing thru its center. For example, the equator as well as the meridian are big circles.

**2.15. Spherical Crofton formula.** *The length of any curve  $\alpha$  in the unit sphere is  $\pi$  times the average number of its crossings with big circles.*

*More presciently, given a unit vector  $u$ , denote by  $n_\alpha(u)$  the number of crossings of  $\alpha$  and the equator with pole at  $u$ . Then*

$$\text{length } \alpha = \overline{n_\alpha(u)}.$$

*Equivalently,*

$$\text{length } \alpha = \overline{\text{length } \alpha_u},$$

*where  $\alpha_u$  denotes the curve obtained by closest point projection of  $\alpha$  to the equator with pole at  $u$ .*

**2.16. Exercise.** *Come up with a Crofton formulas for curves in the Euclidean space via projections to lines and to planes. Find the coefficients in these formulas.*

## 2.5 Applications

*Alternative proof of Proposition 2.6.* Note that

$$\text{length } \beta_u \geq \text{length } \alpha_u$$

for any unit vector  $u$ . Indeed  $\alpha_u$  runs back and forth along a line segment and  $\beta_u$  has to run at least that much.

It follows that

$$\overline{\text{length } \beta_u} \geq \overline{\text{length } \alpha_u}.$$

It remains to apply the Crofton formula. □

Recall that the diameter of a plane figure  $F$  is defined as the least upper bound on the distances between pairs of its points; that is,

$$\text{diam } F = \sup \{ |x - y| : x, y \in F \}.$$

The equilateral triangle with side 1 gives an example of a convex figure of diameter 1 that cannot be covered by a round disc of diameter 1.

**2.17. Exercise.** Assume  $F$  is a convex figure of diameter 1 and  $D$  is the round disc of diameter 1. Show that

$$\text{perim } F \leq \text{perim } D.$$

A convex figure  $F$  has constant width  $a$  if the orthogonal projection of  $F$  to any line has length  $a$ . There are many non-circular shapes of constant width. A nontrivial example is the Reuleaux triangle shown on the picture; it is the intersection of three round disks of the same radius, each having its center on the boundary of the other two. The following exercise is the so called Barbier's theorem.

**2.18. Exercise.** Show that figures with constant width  $a$  have the same perimeter (which equals  $\pi \cdot a$  — the perimeter of the round disc of diameter  $a$ ).

**2.19. Exercise.** Let  $\gamma$  be a closed curve in the unit sphere of length shorter than  $2 \cdot \pi$ . Show that  $\gamma$  lies in a hemisphere.

**2.20. Exercise.** Let  $\alpha$  be a closed curve of length  $\pi$ . Show that it lies between a pair of parallel lines at distance 1 from each other.

**2.21. Exercise.** A spaceship flies around a nonrotating planet of unit radius and comes back to the original position; it was able to make a picture of every point on the surface of the planet.

Try to use the Crofton formulas to get a lower bound on the length of its trajectory (does not need to be exact, but should be larger than  $2 \cdot \pi$ ).

What do you think could be the shortest trajectory?

The Hausdorff distance  $d_H(F, G)$  between two closed bounded sets  $F$  and  $G$  in the plane is defined as the exact lower bound on  $\varepsilon > 0$  such that the  $\varepsilon$ -neighborhood of  $F$  contains  $G$  and the  $\varepsilon$ -neighborhood of  $G$  contains  $F$ .

**2.22. Exercise.** Assume  $F$  and  $G$  are two closed convex figures on the plane such that  $d_H(F, G) < \varepsilon$ . Show that

$$|\text{perim } F - \text{perim } G| < 2 \cdot \pi \cdot \varepsilon.$$

Given two sets  $A$  and  $B$  on the plane, the set  $C$  is called their *Minkowski sum* (briefly  $C = A + B$ ) if  $C$  is formed by adding each vector in  $A$  to each vector in  $B$ ; that is,

$$C = \{a + b : a \in A, b \in B\}.$$

Note that if  $A$  and  $B$  are convex then so is  $C = A + B$ .

Indeed,  $A$  is convex if and only if for any pair of points  $a_0, a_1 \in A$  and any  $t \in [0, 1]$ , the point  $a_t = (1 - t) \cdot a_0 + t \cdot a_1$  belongs to  $A$ . Similarly,  $B$  is convex if and only if for any pair of points  $b_0, b_1 \in B$  and any  $t \in [0, 1]$ , the point  $b_t = (1 - t) \cdot b_0 + t \cdot b_1$  belongs to  $A$ .

Fix a pair of points  $c_0, c_1 \in C$ ; by the definition of Minkowski sum, there are two pairs of points  $a_0, a_1 \in A$  and  $b_0, b_1 \in B$  such that  $c_0 = a_0 + b_0$  and  $c_1 = a_1 + b_1$ . Then

$$\begin{aligned} c_t &= (1 - t) \cdot c_0 + t \cdot c_1 = \\ &= (1 - t) \cdot (a_0 + b_0) + t \cdot (a_1 + b_1) = \\ &= [(1 - t) \cdot a_0 + t \cdot a_1] + [(1 - t) \cdot b_0 + t \cdot b_1] = \\ &= a_t + b_t. \end{aligned}$$

That is,  $c_t \in C$  for any  $t \in [0, 1]$ , hence the result.

**2.23. Exercise.** Show that

$$\text{perim}(A + B) = \text{perim } A + \text{perim } B$$

for any pair of convex figures in the plane.

**2.24. Exercise.** Use Exercise 2.23 and Lemma 2.7 to give another solution of Exercise 2.22.

**2.25. Exercise.** Let  $\gamma$  be a curve that lies in a convex figure  $F$  in the plane.

Let  $\gamma$  be a curve that lies inside a convex figure  $F$  on the plane. Assume that

$$2 \cdot \text{length } \gamma \geq n \cdot \text{perim } F$$

for some integer  $n$ . Show that there is a line  $\ell$  that intersects  $\gamma$  in at least  $n$  distinct points.

**AFTER THIS LINE READ AT YOUR OWN RISK!!!**

# Chapter 3

## Total curvature

### 3.1 Smooth regular curves

Here we introduce the so called *total curvature of curve*. In general term *curvature* is used for something that measures how a geometric object deviates from being a straight; total curvature is not an exception — as you will see if the total curvature of a curve is vanishing then the curve runs along a straight line.

Let  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  be a *smooth regular curve* — smooth means that the velocity vector  $\alpha'(t)$  is defined and continuous with respect to  $t$  and regular means that  $\alpha'(t) \neq 0$  for any  $t$ . If the curve  $\alpha$  is closed then we assume in addition that  $\alpha'(a) = \alpha'(b)$ .

Denote by  $\tau(t)$  the unit vector in the direction of  $\alpha'(t)$ ; that is,  $\tau(t) = \frac{\alpha'(t)}{|\alpha'(t)|}$ . The  $\tau: [a, b] \rightarrow \mathbb{S}^2$  is an other curve which is called *tangent indicatrix* of  $\alpha$ . The length of  $\tau$  is called *total curvature of  $\alpha$* ; that is,

$$\text{TotCurv } \alpha := \text{length } \tau.$$

**3.1. Exercise.** *Show that*

$$\text{TotCurv } \alpha \geq 2 \cdot \pi$$

*for any smooth closed regular curve  $\alpha$ .*

*Moreover, the equality holds if and only if  $\alpha$  is a closed and convex curve that lies in a plane.*

The above exercise is the so called Fenchel's theorem.

## 3.2 General definition

The total curvature of a polygonal line is defined as the sum of its external angles.

More precisely, for a polygonal line  $\beta = p_0 \dots p_n$ , the external angle at the vertex  $p_i$  is defined as  $\alpha_i = \pi - \angle p_{i-1}p_i p_{i+1}$ . The total curvature of the polygonal line  $\beta = p_0 \dots p_n$  is defined as the sum

$$\text{TotCurv } \beta = \alpha_1 + \dots + \alpha_{n-1};$$

it is defined if the polygonal line is *nondegenerate*; that is,  $p_{i-1} \neq p_i$  for any  $i$ .

If the polygonal line  $p_0 \dots p_n$  is closed; that is  $p_0 = p_n$  you add one more angle

$$\alpha_0 + \alpha_1 + \dots + \alpha_{n-1},$$

where  $\alpha_0 = \pi - \angle p_n p_0 p_1$ .

One can define the tangent indicatrix for a polygonal line  $\beta$  as a spherical polygonal line (each edge is an arc of big circle of the sphere) that vertexes are unit vectors  $\xi_1, \dots, \xi_n$  in the directions of  $p_1 - p_0, p_2 - p_1, \dots, p_n - p_{n-1}$  correspondingly; if the polygonal line is closed then we add one more vertex  $\xi_0$  in the directions of  $p_0 - p_n$  and two more edges  $\xi_0 \xi_1$  and  $\xi_n \xi_0$  so the indicatrix of closed polygonal line is a closed spherical polygonal line.

Note that the total curvature of polygonal line is the length of its tangent indicatrix.

**3.2. Exercise.** Let  $a, b, c, d$  and  $x$  be distinct points in  $\mathbb{R}^3$ . Show that

$$\text{TotCurv } abcd \geq \text{TotCurv } abxcd.$$

**3.3. Exercise.** Use Exercise 3.2 to prove an analog of Fenchel's theorem (Exercise 3.1) for closed polygonal lines.

Let  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  be a curve and  $a = t_0 < \dots < t_n = b$  a partition. Set  $p_i = \alpha(t_i)$ . Then the polygonal line  $p_0 \dots p_n$  is called inscribed in  $\alpha$ .

We gave two definitions of total curvature: the first one is given in Section 3.1 via tangent indicatrix — it works for smooth regular curves; the second, via external angles — it works for polygonal lines. The latter can be used to define total curvature of arbitrary curves.

**3.4. Definition.** The total curvature of a nonconstant curve  $\alpha$  is the exact upper bound on the total curvatures of inscribed nondegenerate polygonal lines; if the curve is closed then we assume that the inscribed polygonal lines are closed as well.

We need to assume that the curve is nonconstant, otherwise it does not admit inscribed polygonal lines that are not trivial.

**3.5. Exercise.** *Show that the total curvature is lower semi-continuous with respect to pointwise convergence of curves. That is, if a sequence of curves  $\alpha_n: [a, b] \rightarrow \mathbb{R}^3$  converges pointwise to a curve  $\alpha_\infty: [a, b] \rightarrow \mathbb{R}^3$ , then*

$$\liminf_{n \rightarrow \infty} \text{TotCurv } \alpha_n \geq \text{TotCurv } \alpha_\infty.$$

*Hint:* Modify the proof of semi-continuity of length (Theorem 2.9).

The following definition tells that these two definitions agree.

**3.6. Theorem.** *For smooth regular curves the two definitions of total curvature agree; that is, for any regular curve, the length of its tangent indicatrix is equal to the exact upper bound on the total curvatures of inscribed nondegenerate polygonal lines.*

Note that from the theorem and Exercise 3.3, we get a generalization of Fenchel's theorem (Exercise 3.1) — it works for arbitrary closed curves, not necessary smooth and regular.

**3.7. Lemma.** *Let  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  be a smooth regular curve. Consider three unit vectors  $\lambda$ ,  $\mu$  and  $\nu$  in the directions of  $\alpha'(a)$ ,  $\alpha(b) - \alpha(a)$  and  $\alpha'(b)$  correspondingly. Then*

$$\text{TotCurv } \alpha \geq \angle(\lambda, \mu) + \angle(\mu, \nu).$$

*Proof.* The tangent indicatrix  $\tau$  runs from  $\lambda$  to  $\nu$  in the unit sphere  $\mathbb{S}^2$ .

Note that  $\tau$  can not be separated from  $\mu$  by an equator. Indeed the vector

$$\alpha(b) - \alpha(a) = \int_a^b \alpha'(t) \cdot dt$$

points in the same direction as  $\mu$ . Therefore if the indicatrix  $\tau = \frac{\alpha'}{|\alpha'|}$  lies in a hemisphere then  $\mu$  lies in the same hemisphere.

Fix an equator  $\ell$  in general position. If  $\ell$  intersects the spherical polygonal line  $\lambda\mu\nu$  at one point, then  $\ell$  separates  $\lambda$  from  $\nu$  and therefore it must intersect  $\tau$ . If  $\ell$  intersects the spherical polygonal line  $\lambda\mu\nu$  at two points, then  $\ell$  separates  $\mu$  from  $\lambda$  and  $\nu$  and therefore it must intersect  $\tau$  at two points —  $\tau$  must cross  $\ell$  and then come back. It follows that for almost all equators the number of intersections with

the spherical polygonal line  $\lambda\mu\nu$  can not exceed the number of intersections with  $\tau$ . By the spherical Crofton formula (2.15),  $\tau$  is longer than the spherical polygonal line  $\lambda\mu\nu$ . But the polygonal line  $\lambda\mu\nu$  has length  $\angle(\lambda, \mu) + \angle(\mu, \nu)$ , hence the result.  $\square$

Let us sketch an alternative proof of the lemma which is built on Fenchel's theorem.

*An alternative proof of the lemma.* Note that the curve  $\alpha$  can be extended to a smooth regular closed curve  $\hat{\alpha}$  by an arc  $\beta$  that starts from  $\alpha(b)$  in the same direction as  $\alpha$  turns and joins the segment  $[\alpha(b), \alpha(a)]$  runs along the segment close to  $\alpha(a)$  turns and joints  $\alpha$  smoothly at  $\alpha(a)$ .

Note that the total curvature of  $\beta$  can be made arbitrary close to  $2\pi - \angle(\lambda, \mu) - \angle(\mu, \nu)$ . Indeed,  $\beta$  needs a bit more than  $\pi - \angle(\mu, \nu)$  to turn and join the segment  $[\alpha(b), \alpha(a)]$  and bit more than  $\pi - \angle(\lambda, \mu)$  to turn and join the segment  $\alpha$ .

By Fenchel's theorem,

$$\text{TotCurv } \hat{\alpha} \geq 2\pi.$$

Evidently

$$\text{TotCurv } \hat{\alpha} = \text{TotCurv } \alpha + \text{TotCurv } \beta,$$

hence the lemma follows.  $\square$

*Proof of 3.6.* Let  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  be a smooth curve. Fix a partition  $a = t_0 < \dots < t_n = b$  and consider the corresponding inscribed polygonal line  $\beta = w_0 \dots w_n$ . Let  $\chi = \xi_1 \dots \xi_n$  be its tangent indicatrix — this is a spherical polygonal line; we assume that  $\chi(t_i) = \xi_i$  and it has constant speed on each arc.

Consider a sequence of finer and finer partitions, denote by  $\beta_n$  and  $\chi_n$  the corresponding inscribed polygonal line and its tangent indicatrix; since  $\alpha$  is smooth, the  $\chi_n$  converges pointwise to the  $\tau$  — the tangent indicatrix of  $\alpha$ . By semi-continuity of length functional, we get that

$$\begin{aligned} \text{TotCurv } \alpha &= \text{length } \tau \leq \\ &\leq \varliminf_{n \rightarrow \infty} \text{length } \chi_n = \\ &= \varliminf_{n \rightarrow \infty} \text{TotCurv } \beta_n \leq \\ &\leq \sup\{\text{TotCurv } \beta\}, \end{aligned}$$

where the list upper bound is taken for all partitions and corresponding inscribed polygonal lines  $\beta$ .

It remains to prove that

$$\textcircled{1} \quad \text{TotCurv } \alpha \geq \text{TotCurv } \beta,$$

for any polygonal line  $\beta$  inscribed in  $\alpha$ . Let  $\zeta_i$  be the unit vector in the direction of  $\alpha'(t_i)$ . Consider the spherical polygonal line  $\gamma = \zeta_0 \zeta_1 \zeta_1 \zeta_2 \dots \zeta_n \zeta_n$ ; recall that  $\chi = \xi_0 \dots \xi_n$ . By triangle inequality,

$$\text{length } \gamma \geq \text{length } \chi = \text{TotCurv } \beta.$$

By Lemma 3.7,

$$\text{TotCurv } \alpha \geq \text{length } \gamma,$$

hence  $\textcircled{1}$  follows.  $\square$

### 3.3 Crofton again

Given a curve  $\alpha$  in  $\mathbb{R}^3$  and a unit vector  $u$ , denote by  $\alpha_{u^\perp}$  and  $\alpha_u$  the projection of  $\alpha$  to the plane perpendicular to  $u$  and the line parallel to  $u$  correspondingly.

To prove the following proposition, apply the spherical Crofton formula to the tangent indicatrix of  $\alpha$ .

**3.8. Proposition.** *Let  $\alpha$  be a polygonal line in  $\mathbb{R}^3$ . Show that*

$$\begin{aligned} \text{TotCurv } \alpha &= \overline{\text{TotCurv } \alpha_{u^\perp}} = \\ &= \overline{\text{TotCurv } \alpha_u}. \end{aligned}$$

Note that since the curve  $\alpha_u$  runs back and forth along one line. Each change of its direction contributes  $\pi$  to the total curvature of  $\alpha_u$ . Therefore the total curvature of  $\alpha_u$  is  $n \cdot \pi$ , where  $n$  is the number of switches of the direction. Since  $n$  has to be even,  $\text{TotCurv } \alpha_u$  may take values  $2 \cdot \pi$ ,  $4 \cdot \pi$ ,  $6 \cdot \pi$  and so on.

**3.9. Exercise.** *Use the proposition and the observation above to give yet another proof of Fenchel's theorem (Exercise 3.1).*

### 3.4 DNA inequality

**3.10. Theorem.** *Let  $\alpha$  be a closed curve that lies in a unit disc. Then*

$$\text{TotCurv } \alpha \geq \text{length } \alpha.$$

Note that if  $\text{length } \alpha \leq 2 \cdot \pi$ , then Fenchel's theorem gives a better estimate, for longer curves it gives something new.

*Proof.* Assume  $\alpha$  is a polygonal line.

Fix a unit vector  $u$ . Note that the curve  $\alpha_u$  can run at most length 2 in one direction; therefore the number of turns has to be at least  $\frac{1}{2} \cdot \text{length } \alpha$ . Since each turn of  $\alpha_u$  contributes  $\pi$  to its total curvature, we get

$$\text{TotCurv } \alpha_u \geq \frac{\pi}{2} \cdot \text{length } \alpha_u.$$

The same inequality holds for the average values of left and right hand sides; that is,

$$\overline{\text{TotCurv } \alpha_u} \geq \frac{\pi}{2} \cdot \overline{\text{length } \alpha_u}.$$

Applying the Crofton's formula and Proposition 3.8 we get the result.

It remains to reduce the general case to polygonal lines. Let us inscribe a polygonal line  $\beta$  in  $\alpha$  with length sufficiently close to length of  $\alpha$ ; that is, given  $\varepsilon > 0$ , we choose an inscribed polygonal line  $\beta$  such that

$$\text{length } \alpha < \text{length } \beta + \varepsilon.$$

By the definition of total curvature (3.4) and from above

$$\begin{aligned} \text{TotCurv } \alpha &\geq \text{TotCurv } \beta \geq \\ &\geq \text{length } \beta > \\ &> \text{length } \alpha - \varepsilon. \end{aligned}$$

The statement follows since  $\varepsilon$  is arbitrary positive number.  $\square$

*Alternative proof.* The same argument as above shows that it is sufficient to consider a closed polygonal lines  $\beta = p_0 p_1 \dots p_{n-1}$  in the unit disc. We assume that  $p_n = p_0$ ,  $p_{n+1} = p_1$  and so on. Denote by  $\alpha_i$  the external angle at  $p_i$ .

Denote by  $o$  the center of the disc. Consider a sequence of triangles

$$\triangle q_0 q_1 s_0 \cong \triangle p_0 p_1 o, \triangle q_1 q_2 s_0 \cong \triangle p_1 p_2 o, \dots$$

such that the points  $q_0, q_1 \dots$  lie on one line in the same order and the points  $s_i$  lie on one side from this line.

Note that

$$|s_n - s_0| = \text{length } \beta.$$

Therefore

$$|s_0 - s_1| + \cdots + |s_{n-1} - s_n| \geq \text{length } \beta.$$

Note that

$$|q_i - s_{i-1}| = |q_i - s_i| = |p_i - o| \leq 1$$

and

$$\angle s_{i-1} q_i s_i \leq \alpha_i$$

for each  $i$ . Therefore

$$|s_{i-1} - s_i| < \alpha_i$$

for each  $i$ .

It follows that

$$\begin{aligned} \text{TotCurv } \beta &= \alpha_1 + \cdots + \alpha_n \geq \\ &\geq |s_0 - s_1| + \cdots + |s_{n-1} - s_n| \geq \\ &\geq \text{length } \beta. \end{aligned}$$

Hence the result.  $\square$

## 3.5 Curves of finite total curvature

**3.11. Exercise.** Assume that a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  has finite total curvature. Show that  $\alpha$  is rectifiable.

We say that a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  *does not stop* if  $\alpha$  is not constant on any subinterval of  $[a, b]$ .

**3.12. Exercise.** Assume that the curve  $\alpha$  does not stop and its total curvature is less than  $\pi$ . Show that  $\alpha$  is simple; that is it has no self-intersections.

**3.13. Exercise-definition.** Assume that a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  does not stop and has finite total curvature. Show that the direction of exit and entrance is defined for any point.

That is for any  $t_0 \in [a, b)$  the unit vector

$$v(\varepsilon) = \frac{\alpha(t_0 + \varepsilon) - \alpha(t_0)}{|\alpha(t_0 + \varepsilon) - \alpha(t_0)|}$$

converges as  $\varepsilon \rightarrow 0^+$ ; its limit is called the direction of exit and it will be denoted by  $\alpha^+(t_0)$

Analogously, for any  $t_0 \in (a, b]$  the unit vector

$$w(\varepsilon) = \frac{\alpha(t_0 - \varepsilon) - \alpha(t_0)}{|\alpha(t_0 - \varepsilon) - \alpha(t_0)|}$$

converges as  $\varepsilon \rightarrow 0^+$ ; its limit is called the direction of entrance and it will be denoted by  $\alpha^-(t_0)$ .

**3.14. Exercise.** Assume that a curve  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  does not stop and has finite total curvature. Show that

$$\alpha^+(t) = -\alpha^-(t)$$

at all  $t \in [a, b]$  except a countable subset.

**3.15. Exercise.** Assume a sequence of curves  $\alpha_n: [a, b] \rightarrow \mathbb{R}^3$  converges to a curve  $\alpha_\infty: [a, b] \rightarrow \mathbb{R}^3$  and

$$\lim_{n \rightarrow \infty} \text{length } \alpha_n > \text{length } \alpha_\infty.$$

Show that

$$\text{TotCurv } \alpha_n \rightarrow \infty \quad \text{as } n \rightarrow \infty.$$

## 3.6 Total signed curvature

Let us define *total signed curvature* for polygonal line in the plane as a sum of signed external angles; the external angle has positive sign if the line turns right and negative sign if the line turns left; the signed external angle is undefined if a pair of adjacent edges overlap; that is if at one vertex the polygonal line turns in the opposite direction. In particular the total signed curvature is defined for any simple polygonal line in the plane.

**3.16. Exercise.** Assume that the total signed curvature of a closed polygonal line in the plane is defined. Show that it is multiple of  $2\pi$ .

**3.17. Exercise.** Show that total signed curvature of any closed simple polygonal line in the plane is  $\pm 2\pi$ .

## Chapter 4

# Fáry–Milnor theorem

### 4.1 Tame knots

It is tricky to make a formal definition that captures the intuitive meaning of *knot*. An attempt to define knots as simple closed curves leads to pathological examples as the one shown on the diagram — these are so called *wild knots*. If one adds that the curve has to be

smooth and regular, then these examples disappear, but it is still a tricky to give right definition of *deformation* — the following diagram shows that it can not be defined as a continuous family of closed simple

smooth regular curves. Observe that all curves on the diagram are smooth and regular for all times including the last moment.

We define a *knot* (more precisely *tame knot*) as a simple closed polygonal line in Euclidean space  $\mathbb{R}^3$ .

The notation  $\triangle abc$  is used for triangle  $abc$ ; that is a polygonal line with three edges and vertexes  $a$ ,  $b$  and  $c$ . Let us denote by  $\blacktriangle abc$  the convex hull of the points  $a$ ,  $b$  and  $c$ ;  $\blacktriangle abc$  is the solid triangle with the vertexes  $a$ ,  $b$  and  $c$ . The points  $a$ ,  $b$  and  $c$  are assumed to be distinct, but they might lie on one line; that is, for us a degenerate triangle is a triangle.

We understand a *triangular isotopy* of a knot to be the generation of a new knot from the original one by means of the following two operations:

Assume  $[pq]$  is an edge of the knot and  $x$  is a point such that the solid triangle  $\blacktriangle pqx$  has no common points with the knot except for the edge  $[pq]$ . Then we can replace the edge  $[pq]$  in the knot by two adjacent edges  $[px]$  and  $[qx]$ .

We can also perform the inverse operation. That is, if for two adjacent edges  $[px]$  and  $[qx]$  of a knot the triangle  $\blacktriangle pqx$  has no common points with the knot except for the points on the edges  $[px]$  and  $[qx]$ , then we can replace two adjacent edges  $[px]$  and  $[qx]$  by one edge  $[pq]$ .

Polygons that arise from one another by a finite sequence of triangular isotopies are called *isotopic*.

A knot that is not isotopic to a triangle is called nontrivial.

The trefoil knot shown on the diagram gives a simple example of nontrivial knot. A proof that the trefoil knot is nontrivial can be found in any textbook on knot theory, we do not give it here. The most elementary and visual proof is based on the so called *tricolorability* of knot diagrams.

**4.1. Exercise.** Let  $x$  and  $y$  be two points on the adjacent edges  $[p_1p_2]$  and  $[p_2p_3]$  of a knot  $\beta = p_1p_2p_3 \dots p_n$ . Assume that the solid triangle  $\blacktriangle xp_2y$  intersects  $\beta$  only along the  $[xp_2] \cup [p_2y]$ . Show that the knot  $\beta' = p_1xyp_3 \dots p_n$  is isotopic to  $\beta$ .

## 4.2 Fáry–Milnor theorem

We will give few proofs of the following theorem.

**4.2. Theorem.** The total curvature of any nontrivial knot is at least  $4\pi$ .

The famous Fáry–Milnor theorem states that the inequality is strict; that is, the total curvature of any nontrivial knot *exceeds*  $4\pi$ . It is easy to construct a trefoil knot with total curvature arbitrary close to  $4\pi$ ; therefore this result is optimal.

The question was raised by Karol Borsuk [3] and answered independently by István Fáry and John Milnor [4, 5]; latter few other proofs were found.

### 4.3 Milnor's proof

In the proof we will use the following fact.

**4.3. Proposition.** *Assume that a height function  $(x, y, z) \rightarrow z$  has only one local minimum and one local maximum on a closed simple polygonal line and all the vertexes of the polygonal line lie on different height. Then the line is a trivial knot.*

The proof is a simple application of the definition of isotopy, given in the previous section.

*Proof.* Let  $\beta = p_1 \dots p_n$  be the closed simple polygonal line such that the height function  $(x, y, z) \rightarrow z$  has one local minimum one local maximum. Note that on each of the two arcs of  $\beta$  from min-vertex to max-vertex the height function increases monotonically.

Consider three vertexes with the largest value of the height function; they have to include the max-vertex and two more. Note that these three vertexes are consequent in the polygonal line; without loss of generality we can assume that they are  $p_{n-1}, p_n, p_1$ .

Note that the solid triangle  $\triangle p_{n-1}p_np_1$  does not intersect any edge  $\beta$  except the two adjacent edges  $[p_{n-1}p_n] \cup [p_np_1]$ . Indeed, if  $\triangle p_{n-1}p_np_1$  intersects  $[p_1p_2]$ , then, since  $p_2$  lies below  $\triangle p_{n-1}p_np_1$ ,  $[p_1p_2]$  must intersect  $[p_{n-1}p_n]$  which is impossible since  $\beta$  is simple. The same way one can show that  $\triangle p_{n-1}p_np_1$  can not intersect  $[p_{n-2}p_{n-1}]$ . The remaining edges lie below  $\triangle p_{n-1}p_np_1$ , hence they can not intersect this triangle.

Applying triangular isotopy, to  $\triangle p_{n-1}p_np_1$  we get a closed simple polygonal line  $\beta' = p_1 \dots p_{n-1}$  which is isotopic to  $\beta$ .

Since all the vertexes  $p_i$  have different height, the assumption of proposition holds for  $\beta'$ .

Repeating this procedure  $n - 3$  times we get a triangle. Hence  $\beta$  is a trivial knot.  $\square$

*Milnor's proof of 4.2.* Let  $\alpha$  be a simple closed polygonal line. Assume its total curvature is less than  $4 \cdot \pi$ . Then by Proposition 3.8,

$$\text{TotCurv } \alpha_u < 4 \cdot \pi$$

for some unit vector  $u$ . Moreover, we can assume that  $u$  points in a generic direction; that is,  $u$  is not perpendicular to any edge or diagonal of  $\alpha$ .

The total curvature of  $\alpha_u$  is  $\pi$  times the number of turns of  $\alpha_u$  which has to be an even number. It follows that number of turns of  $\alpha_u$  is at most 2; it can not be less than 2 for generic direction and therefore it is 2.

That is, if we rotate the space so that  $u$  points to the top, then the height function has exactly one minimum and one maximum; by Proposition 4.3,  $\alpha$  is a trivial knot — hence the result.  $\square$

## 4.4 Fáry's proof

Let us give a sketch of another proof, based on the original idea of István Fáry.

*Fáry's proof of 4.2.* Consider a projection of the knot to a plane in general position. That is, we assume that the self-intersections of the projection are at most double and the projection of each edge does not degenerate. The obtained closed polygonal line  $\beta = p_1 p_2 \dots p_n$  divides the plane into domains, one of which is unbounded, denote it by  $U$ , and the others are bounded.

First note that all domains can be colored in a chessboard order; that is, they can be colored in black and white in such a way that domains with common borderline get different colors. If the unbounded domain gets white color and every other domain is black then one can untie the knot by flipping these domains one by one.

**4.4. Exercise.** Give a formal proof of the last statement; that is, show that if only unbounded domain is white then  $\beta$  is isotopic to a triangle.

Therefore among the bounded domains there is a white domain, denote it by  $D$ . The domain  $D$  can not have a borderline with  $U$  since they have the same color. Fix a point  $o$  in this domain.

For each  $i$ , set

$$\begin{aligned}\varphi_i &= \pi - \angle p_{i-1}p_i p_{i+1}, \\ \psi_i &= \angle p_{i-1}op_i, \\ \theta_i &= \angle op_i p_{i+1}.\end{aligned}$$

Here indexes are taken modulo  $n$ ; in particular,  $p_n = p_0$ .

Note that  $\varphi_i$  is the external angle at  $p_i$ ; therefore

$$\text{TotCurv } \beta = \varphi_1 + \cdots + \varphi_n$$

Direct calculations show that

$$\varphi_i \geq \psi_i + \theta_{i-1} - \theta_i.$$

In the two pictures below,  $\varphi_i$  is the solid angle; the rest of angles  $\psi_i$ ,  $\theta_{i-1}$  and  $\theta_i$  are the same. We have equality on the first picture and strict inequality on the second picture.

It follows that

$$\varphi_1 + \cdots + \varphi_n \geq \psi_1 + \cdots + \psi_n.$$

The last sum is the total angle at which  $\beta$  is seen from  $o$  counted with multiplicity. The boundary of  $D$  contributes at least  $2\pi$  to this sum and the boundary of  $U$  contributes another  $2\pi$ ; since their boundaries do not overlap we get

$$\psi_1 + \cdots + \psi_n \geq 4\pi,$$

hence the result.

This is true for the projection of the knot to any plane in general position. The remaining planes contribute nothing to the average value. Therefore by Proposition 3.8, the total curvature of the original knot is at least  $4\pi$ .  $\square$

**4.5. Exercise.** *Construct a closed smooth simple curve with total curvature arbitrary close to  $2\pi$  such that its projection to any plane has at least 10 self-intersections.*

## 4.5 Proof of Alexander and Bishop

Here we sketch a proof of Fáry–Milnor theorem given by of Stephanie Alexander and Richard Bishop in [6].

The proof is elementary, but not simple (elementary does not mean simple, it means only that it does not use much theory). It is based on the following two facts that we already familiar with:

- ◊ If a closed polygonal line  $\beta'$  is inscribed in a closed polygonal line  $\beta$  then

$$\text{TotCurv } \beta' \leq \text{TotCurv } \beta.$$

- ◊ The total curvature of doubly covered bigon is  $4 \cdot \pi$ ; that is,

$$\text{TotCurv } \beta = 4 \cdot \pi$$

if  $\beta = pqpq$  for two distinct points  $p$  and  $q$ . Similarly if a quadrilateral is sufficiently close to a doubly covered bigon, then its total curvature is close to  $4 \cdot \pi$ .

*Proof.* Let  $\beta = p_1 \dots p_n$  be a closed polygonal line that is not a trivial knot; that is, one can not get a triangle from  $\beta$  by applying a sequence of triangular isotopies defined in the previous section.

We proceed by induction on the number  $n \geq 3$ . In the base case  $n = 3$  the polygonal line  $\beta$  is a triangle. Therefore, by the definition,  $\beta$  is a trivial knot — nothing to prove.

Consider the smallest  $n$  for which the statement fail; that is, there is a closed simple polygonal line  $\beta = p_1 \dots p_n$  that is not a trivial knot such that

$$\text{①} \quad \text{TotCurv } \beta < 4 \cdot \pi.$$

We use the indexes modulo  $n$  that is  $p_0 = p_n$ ,  $p_1 = p_{n+1}$  and so on. Without loss of generality, we may assume that  $\beta$  is in general position; that is, no four vertexes of  $\beta$  lie on one plane.

Set  $\beta_0 = \beta$ . If the solid triangle  $\blacktriangle p_0 p_1 p_2$  intersects  $\beta_0$  only by the two adjacent edges, then applying the corresponding triangular isotopy, we get a knot  $\beta'_0$  with  $n - 1$  edge that is inscribed in  $\beta_0$  therefore

$$\text{TotCurv } \beta_0 \geq \text{TotCurv } \beta'_0.$$

On the other hand by induction hypothesis

$$\text{TotCurv } \beta'_0 \geq 4 \cdot \pi$$

which contradicts ①.

Choose the first point  $w'_1$  on the edge  $[p_1 p_2]$  so that the line segment  $[p_0 w'_1]$  intersects  $\beta_0$ . Denote a point of intersection by  $y_1$ .

Choose a point  $w_1$  on  $[p_1p_2]$  a bit before  $w'_1$  (below we explain how close). Denote by  $x_1$  the point on  $[p_0w_1]$  that minimize the distance to  $y_1$ . This way we get a closed polygonal line  $\beta_1 = w_1p_2 \dots p_n$  with two marked points  $x_1$  and  $y_1$ . Denote by  $m_1$  the number of edges in the arc  $y_1w_1 \dots x_1$  of  $\beta_1$ .

By Exercise 4.1,  $\beta_1$  is isotopic to  $\beta_0$ ; in particular  $\beta_1$  is a nontrivial knot.

Now let us repeat the procedure for the adjacent edges  $[w_1b_2]$  and  $[b_2b_3]$  of  $\beta_1$ . If the solid triangle  $\blacktriangle w_1b_2b_3$  intersects  $\beta_1$  only at these two adjacent edges, then we get a contradiction with the induction hypothesis the same way as before. Otherwise we get a new knot  $\beta_2 = w_1w_2b_3 \dots b_n$  with two marked points  $x_2$  and  $y_2$ . Denote by  $m_2$  the number of edges in the broken line  $y_2w_3 \dots x_2$ .

Note that the points  $x_1, x_2, y_1, y_2$  can not appear on  $\beta_2$  in the same cyclic order; otherwise the broken line  $x_1x_2y_1y_2$  can be made to be arbitrary close to a doubly covered bigon which again contradicts ❶.<sup>1</sup>

Therefore we can assume that the arc  $x_2w_2 \dots y_2$  lies inside of arc  $x_1w_1 \dots y_1$  in  $\beta_2$  and therefore  $m_1 > m_2$ .

Continuing this procedure we get a sequence of polygonal lines  $\beta_i = w_1 \dots w_i p_{i+1} p_n$  with marked points  $x_i$  and  $y_i$  such that the number of edges  $m_i$  from  $x_i$  to  $y_i$  decreases in  $i$ . Clearly  $m_i > 1$  for any  $i$  and  $m_1 < n$ . Therefore it requires less than  $n$  steps we get a contradiction with the induction hypothesis.  $\square$

**4.6. Exercise.** Suppose that a closed curve  $\alpha$  crosses a line at four points  $a, b, c$  and  $d$ . Assume that the points  $a, b, c$  and  $d$  appear on the line in the same order and they appear on the curve  $\alpha$  in the order  $a, c, b, d$ . Show that

$$\text{TotCurv } \alpha \geq 4 \cdot \pi.$$

A line crossing a knot at four points as in the exercise is called *alternating quadriseccants*. It turns out that any nontrivial knot admits

<sup>1</sup>More precisely, the choice of  $w_1$  has to be made so that the distance  $|x_1 - y_1|$  would be much less than all the distances between  $y_1$  and any point  $z \in \beta \cap \blacktriangle p_1 p_2 p_3$ , so we have

$$\angle y_1 z x_1 < \frac{\varepsilon}{10},$$

where  $\varepsilon = 4 \cdot \pi - \text{TotCurv } \beta$ . In this case, since  $y_2 \in \beta \cap \blacktriangle p_1 p_2 p_3$  and  $x_2$  can be taken arbitrary close to  $y_2$ , we have

$$\text{TotCurv } x_1 x_2 y_1 y_2 > 4 \cdot \pi - \varepsilon = \text{TotCurv } \beta$$

which can not happen since  $x_1 x_2 y_1 y_2$  is inscribed in  $\beta$ .

an alternating quadrisecants [7]; it provides yet another proof of Fáry–Milnor theorem.

**4.7. Advanced exercise.** *Show that given any real number  $\Phi$  there is a knot  $\beta$  such that any knot isotopic to  $\beta$  has total curvature at least  $\Phi$ .*

*Hint:* Use that there are knots with arbitrary large *bridge number*, see for example [8] and the references there in.

# Chapter 5

## Plane curves

### 5.1 Signed curvature

Any regular smooth curve can be parametrized by its length. The obtained curve  $\alpha$  (that is the constructed reparametrization of the given curve) has unit speed; that is,  $|\alpha'(t)| = 1$  for any  $t$ . A curve with such parametrization is called *unit-speed* curve or a curve with a *natural parametrization*.

It is straightforward to show any smooth regular curve remains smooth (and regular) after such reparametrization; here smooth means that all the derivatives  $\alpha^{(n)}(t)$  are defined for all values of  $t$  in the domain of definition.

**5.1. Proposition.** *Assume  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  be a smooth unit-speed curve. Then*

$$\alpha'(t) \perp \alpha''(t)$$

*for any  $t$ .*

The scalar product (also known as dot product) of two vectors  $v$  and  $w$  will be denoted by  $\langle v, w \rangle$ . Recall that for derivative of scalar product the product rule holds; that is if  $v = v(t)$  and  $w = w(t)$  are smooth vector-valued functions of real argument  $t$ , then

$$\langle v, w \rangle' = \langle v', w \rangle + \langle v, w' \rangle.$$

*Proof.* Since  $|\alpha'(t)| = 1$ , we have

$$\langle \alpha'(t), \alpha'(t) \rangle = 1.$$

Taking derivative of both sides we get

$$2 \cdot \langle \alpha''(t), \alpha'(t) \rangle = 0,$$

hence the result.  $\square$

Given a vector  $v \in \mathbb{R}^2$  denote by  $i \cdot v$  the vector obtained from  $v$  by the counterclockwise rotation by  $\frac{\pi}{2}$ . (The “multiplication” by  $i$  agrees with the multiplication by imaginary unit if one use complex coordinates on the plane  $z = x + i \cdot y$ .)

Assume  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  be a smooth unit-speed curve. Recall that curvature of  $\alpha$  at  $t$  can be defined as  $|\alpha''(t)|$ .

The *signed curvature*  $\kappa(t)$  is uniquely defined by the identity

$$\alpha''(t) = \kappa(t) \cdot i \cdot \alpha'(t).$$

Note that by Proposition 5.1 this equation has a solution. Since  $|\alpha'(t)|$  we have that  $|\kappa(t)| = |\alpha''(t)|$  for any  $t$ .

The signed curvature measures how fast the direction  $\tau(t) = \alpha'(t)$  rotates; it is positive if it turns left and negative if it turns right; if the curve goes straight then its curvature vanish.

## 5.2 Osculating circline

It is straightforward to prove the following statement.

**5.2. Proposition.** *Given a point  $p$ , a unit vector  $u$  and a real number  $\kappa$  there is unique smooth unit-speed curve  $\gamma: \mathbb{R} \rightarrow \mathbb{R}^2$  that starts at  $p$  in the direction of  $u$  and has constant signed curvature  $\kappa$ .*

*Moreover if  $\kappa = 0$ , then  $\gamma$  is a line  $\gamma = p + t \cdot u$  and if  $\kappa \neq 0$ , then  $\gamma$  runs around a circle of radius  $\frac{1}{|\kappa|}$  with center at  $p + \frac{i}{\kappa} \cdot u$ .*

Further we will use term *circline* for *circle or line*.

**5.3. Definition.** *Let  $\alpha$  be a smooth unit-speed plane curve; denote by  $\kappa(t)$  the signed curvature of  $\alpha$  at  $t$ .*

*A unit-speed plane curve  $\gamma$  of constant signed curvature  $\kappa(t_0)$  that starts at  $\alpha(t_0)$  and runs in the direction  $\alpha'(t_0)$  is called *osculating circline*.*

## 5.3 Supporting circlines

Suppose  $\alpha: [a, b] \rightarrow \mathbb{R}^2$  be a smooth unit-speed plane curve and  $t_0 \in (a, b)$ .

A unit-speed circline  $\gamma$  supports  $\alpha$  at  $t_0$  if  $\alpha(t_0)$  lies on  $\gamma$  and the points  $\alpha(t)$  lie on one closed side of  $\gamma$  for all values  $t$  sufficiently close to  $t_0$ .

The following claim resembles the first derivative test.

**5.4. Claim.** *Suppose a unit-speed circline  $\gamma$  supports a smooth unit-speed plane curve  $\alpha$  at  $t_0$  from right (correspondingly left). Without loss of generality we can assume that  $\gamma(0) = \alpha(t_0)$ .*

*Denote by  $\kappa$  the signed curvature of  $\gamma$  and by  $\kappa(t_0)$  the signed curvature of  $\alpha$  at  $t_0$ . Then  $\gamma'(0) = \pm\alpha'(t_0)$ .*

Otherwise the curve  $\alpha$  would cross  $\gamma$  transversely and therefore could not stay at the same side for values close to  $t_0$ .

Reverting the parametrization of  $\gamma$  if necessary we may (and further will) assume that

$$\gamma'(0) = \alpha'(t_0)$$

holds for any supporting circline  $\gamma$  to  $\alpha$  at  $t_0$ . In this case we say that  $\gamma$  supports  $\alpha$  from right (correspondingly left) if  $\alpha$  lies on left (correspondingly right) side of  $\gamma$ .

The following proposition resembles the second derivative test.

**5.5. Proposition.** *Assume  $\gamma$  is a circle that that supports  $\alpha$  at  $t_0$  from right (correspondingly left). Then*

$$\kappa(t_0) \geq \kappa \quad (\text{correspondingly } \kappa(t_0) \leq \kappa).$$

where  $\kappa$  is the signed curvature of  $\gamma$  and  $\kappa(t_0)$  is the signed curvature of  $\alpha$  at  $t_0$ .

*A partial converse also holds. Namely suppose a unit-speed circline  $\gamma$  with signed curvature  $\kappa$  starts at  $\alpha(t_0)$  in the direction  $\alpha'(t_0)$ . Then  $\gamma$  supports  $\alpha$  at  $t_0$  from the right (correspondingly left) if*

$$\kappa(t_0) > \kappa \quad (\text{correspondingly } \kappa(t_0) < \kappa).$$

*Proof.* We prove only case  $\kappa > 0$ . The 2 remaining cases  $\kappa = 0$  and  $\kappa < 0$  can be done essentially same way.

Since  $\kappa \neq 0$ , the curve  $\gamma$  is a circle (it can not be a line). According to Proposition 5.2,  $\gamma$  has radius  $\frac{1}{\kappa}$  and it is centered at

$$z = \alpha(t_0) + \frac{i}{\kappa} \cdot \alpha'(t_0).$$

Consider the function

$$f(t) = |z - \alpha(t)|^2 - \frac{1}{\kappa^2}.$$

Note that  $f(t) \leq 0$  (correspondingly  $f(t) \geq 0$ ) if and only if  $\alpha(t)$  lies on the closed left (correspondingly right) side from  $\gamma$ . It follows that

◇ if  $\gamma$  supports  $\alpha$  at  $t_0$  from right, then

$$f'(t_0) = 0 \quad \text{and} \quad f''(t_0) \leq 0;$$

◇ if  $\gamma$  supports  $\alpha$  at  $t_0$  from left, then

$$f'(t_0) = 0 \quad \text{and} \quad f''(t_0) \geq 0;$$

◇ if

$$f'(t_0) = 0 \quad \text{and} \quad f''(t_0) < 0,$$

then  $\gamma$  supports  $\alpha$  at  $t_0$  from right;

◇ if

$$f'(t_0) = 0 \quad \text{and} \quad f''(t_0) > 0,$$

then  $\gamma$  supports  $\alpha$  at  $t_0$  from left;

Direct calculations show that

$$\begin{aligned} f(t_0) &= 0; \\ f'(t_0) &= \langle z - \alpha(t), z - \alpha(t) \rangle' |_{t=t_0} = \\ &= -2 \cdot \langle \alpha'(t_0), z - \alpha(t_0) \rangle = \\ &= -2 \cdot \langle \alpha'(t_0), \frac{i}{\kappa} \cdot \alpha'(t_0) \rangle = \\ &= 0; \\ f''(t_0) &= \langle z - \alpha(t), z - \alpha(t) \rangle'' |_{t=t_0} = \\ &= 2 \cdot (\langle \alpha'(t_0), \alpha'(t) \rangle - \langle \alpha''(t_0), z - \alpha(t) \rangle) = \\ &= 2 \cdot \left( 1 - \kappa \cdot \frac{1}{\kappa(t_0)} \right) \end{aligned}$$

Hence the result. □

**5.6. Exercise.** Assume  $\alpha$  is a closed smooth unit-speed plane curve that runs in a unit disk. Show that there is a point on  $\alpha$  with curvature at least 1.

Give two proofs, one based on DNA inequality 3.10 and the other based on Proposition 5.5.

# Appendix A

## Semisolutions

**Exercise 1.5.** First let us show that Dido's problem follows from the isoperimetric inequality.

Assume  $F$  is a figure bounded by a straight line and a curve of length  $\ell$  whose endpoints belong to that line. Let  $F'$  be the reflection of  $F$  in the line. Note that the union  $G = F \cup F'$  is a figure bounded by a closed curve of length  $2 \cdot \ell$ .

Applying the isoperimetric inequality, we get that the area of  $G$  can not exceed the area of round disc with the same circumference  $2 \cdot \ell$  and the equality holds only if the figure is congruent to the disc. Since  $F$  and  $F'$  are congruent, Dido's problem follows.

Now let us show that the isoperimetric inequality follows from the Dido's problem.

Assume  $G$  is a convex figure bounded by a closed curve of length  $2 \cdot \ell$ . Cut  $G$  by a line that splits the perimeter in two equal parts —  $\ell$  each. Denote by  $F$  and  $F'$  the two parts. Applying the Dido's problem for each part, we get that that are of each does not exceed the area of half-disc bounded by a half-circle. The two half-disc could be arranged into a round disc of circumference  $\ell$ , hence the isoperimetric inequality follows.

**Exercise 2.16.** Let  $\alpha: [a, b] \rightarrow \mathbb{R}^3$  be a curve. Given a unit vector  $u$ , denote by  $\alpha_u$  the projection of  $\alpha$  on a line in the direction of  $u$ ; denote by  $\alpha_{u^\perp}$  the of  $\alpha$  on a plane perpendicular to  $u$ .

Two formulas

$$\text{length } \alpha = k \cdot \overline{\text{length } \alpha_u}$$

and

$$\text{length } \alpha = k' \cdot \overline{\text{length } \alpha_{u^\perp}}$$

can be proved the same way as the Crofton's formula in the plane.

It remains to find the coefficients  $k$  and  $k'$ . It is sufficient to calculate the average projection of unit segment to a line and to a plane. We need to find two integrals

$$k = \oint_{\mathbb{S}^2} |x| \cdot d \text{ area}$$

and

$$k' = \oint_{\mathbb{S}^2} \sqrt{1 - x^2} \cdot d \text{ area},$$

where  $\mathbb{S}^2 = \{ (x, y, z) \in \mathbb{R}^3 : x^2 + y^2 + z^2 = 1 \}$  is the unit sphere in the Euclidean space and  $\oint$  denotes the average value — since the area of unit sphere is  $4 \cdot \pi$ , we have

$$\oint_{\mathbb{S}^2} f(x, y, z) \cdot d \text{ area} = \frac{1}{4 \cdot \pi} \cdot \int_{\mathbb{S}^2} f(x, y, z) \cdot d \text{ area}$$

Note that in the cylindrical coordinates

$$(x, \varphi = \arctan \frac{y}{z}, \rho = \sqrt{y^2 + z^2}),$$

we have  $d \text{ area} = dx \cdot d\varphi$ . Therefore

$$k = \oint_{[-1, 1]} |x| \cdot dx = \frac{1}{2}$$

and

$$k' = \oint_{[-1, 1]} \sqrt{1 - x^2} \cdot dx = \frac{\pi}{4}.$$

**Comment.** Note that  $\frac{k'}{k} = \frac{\pi}{2}$  is the coefficient in the 2-dimensional Crofton formula. This is not a coincidence — think about it.

**Exercise 3.1.** Assume contrary, that is there is a closed smooth regular curve  $\alpha$  such that  $\text{TotCurv } \alpha < 2 \cdot \pi$ .

The tangent indicatrix  $\tau$  of  $\alpha$  is a curve in a sphere; by the definition of total curvature, the length of  $\tau$  is the total curvature of  $\alpha$ ; in particular

$$\text{length } \tau < 2 \cdot \pi.$$

By Exercise 2.19,  $\tau$  lies in an open hemisphere. If  $u$  is the center of the hemisphere, then

$$\langle u, \tau(t) \rangle > 0 \quad \text{and therefore} \quad \langle u, \alpha'(t) \rangle > 0$$

for any  $t$ . Therefore the function  $t \mapsto \langle u, \alpha(t) \rangle$  is strictly increasing. In particular, if  $\alpha$  is defined on the time interval  $[a, b]$ , then

$$\langle u, \alpha(a) \rangle < \langle u, \alpha(b) \rangle.$$

But  $\alpha$  is closed; that is  $\alpha(a) = \alpha(b)$  — a contradiction.

Now let us prove the equality case. First note that it is sufficient to show that  $\tau$  runs around an equator.

Assume  $\tau$  is not an equator, from above we know that  $\tau$  can not lie in an open hemisphere. Note that we can shorten  $\tau$  by a small chord. The obtained curve  $\tau'$  is shorter than  $2 \cdot \pi$  and therefore lies in an open hemisphere. Applying this construction for shorter and shorter chord and passing to the limit we get that  $\tau$  lies in closed hemisphere. Denote its center by  $u$  as before, then

$$\langle u, \tau(t) \rangle \geq 0 \quad \text{and therefore} \quad \langle u, \alpha'(t) \rangle \geq 0$$

for any  $t$ . Since  $\alpha$  is closed we have that  $\langle u, \alpha(t) \rangle$  is constant; that is, runs in a plane perpendicular to  $u$  and  $\tau$  lies in an equator perpendicular to  $u$ .

So  $\tau$  is a curve that runs along equator, has length  $2 \cdot \pi$  and does not lie in a open hemisphere. Since  $\tau$  is not an equator, it have to run along half-equator back and forth. In this case  $\tau$  lies in an other closed hemisphere and has some points in its interior. The latter contradicts closeness of  $\alpha$  the same way as above.
